## 18 Abstract

In 2015, the Ethiopian Federal Ministry of Health (FMOH) developed the Saving Lives through Safe Surgery (SaLTS) initiative to improve national surgical care. Previous work led to development and implementation of 15 surgical key performance indicators (KPIs) to standardize surgical data practices. The objective of this project is to investigate current practices of KPI data collection and assess quality to improve data management and strengthen surgical systems.

The first portion of the study documented the surgical data collection process including methods, instruments, and effectiveness at 10 hospitals across 2 regions in Ethiopia. Secondly, data for KPIs of focus [1. Surgical Volume, 2. Perioperative Mortality Rate (POMR), 3. Adverse Anesthetic Outcome (AAO), 4. Surgical Site Infection (SSI), and 5. Safe Surgery Checklist (SSC) Utilization] were compared between registries, KPI reporting forms, and the DHIS2 (district health information system) electronic database for a 6-month period (January - June 2022). Quality was assessed based on data completeness and consistency.

32 The data collection process involved hospital staff recording data elements in registries. 33 guality officers calculating KPIs, completing monthly KPI reporting forms, and submitting data 34 into DHIS2 for the national and regional health bureaus. Data guality verifications revealed 35 discrepancies in consistency at all hospitals, ranging from 1-3 indicators. For all hospitals, 36 average monthly surgical volume was 57 cases, POMR was 0.38% (13/3399), inpatient SSI rate 37 was 0.79% (27/3399), AAO rate was 0.15% (5/3399), and mean SSC utilization monthly was 38 93% (100% median). Half of the hospitals had incomplete data within the registries, ranging 39 from 2-5 indicators. AAO, SSC, and SSI were commonly missing data in registries. Non-40 standardized KPI reporting forms contributed significantly to the findings.

3

41 Facilitators to guality data collection included continued use of registries from previous 42 interventions and use of a separate logbook to document specific KPIs. Delayed rollout of these 43 indicators in each region contributed to issues in data guality. Barriers involved variable 44 indicator recording from different personnel, data collection tools that generate false positives 45 (i.e. completeness of SSC defined as paper form filled out prior to patient discharge) or missing 46 data because of reporting time period (i.e. monthly SSI may miss infections outside of one 47 month), inadequate data elements in registries, and lack of standardized monthly KPI reporting 48 forms. As the FMOH introduces new indicators and changes, we recommend continuous and 49 consistent quality checks and data capacity building, including the use of routinely generated 50 health information for quality improvement projects at the department level.

#### 51 Introduction

52 Creating effective global surgery programs requires a clear understanding of the 53 baseline state of surgical care. While the global surgery movement has gained momentum in 54 the past several years, there remains a lack of quality data regarding the status of surgery in 55 low-resource settings [1]. Our understanding of surgical capacity, resources, and outcomes has 56 been limited by our methods of inquiry and the system in place for measuring results.

57 The guest for global surgery data was instigated by the Lancet Commission on Global 58 Surgery, [2] who proposed six core indicators designed to measure access to safe and 59 affordable surgical care. A number of these were integrated into the World Bank's World 60 Development Indicators [3] and the World Health Organization's Global Health Indicators [4]. 61 Based on expert opinion in the Utstein consensus report, the global surgery indicators have 62 since been uniformly defined and narrowed to five (surgical volume, perioperative mortality rate 63 (POMR), surgical workforce, financial risk protection, and geospatial access) [5]. Information on 64 these metrics have come from a variety of methodological approaches in the global community.

4

Literature reviews, modeling studies, facility-based surveys, and regional and international surgical outcomes collaboratives are the diverse sources for these data [6-14]. While these studies have provided the foundation for global surgery indicator benchmarking, there is a growing need for sustainable and timely country-based systems with surgical metrics integrated into national health information systems [15-16].

70 A monitoring and evaluation pillar was included in Ethiopia's national surgical strategy 71 (SaLTS or Saving Lives Through Safe Surgery) to gauge the current surgical practice in the 72 country and create a sustainable method for tracking progress [17-18]. The surgical key 73 performance indicators (KPIs) are 15 metrics prospectively collected and reported regularly from 74 each health facility in the country. In 2018, the indicators were piloted at 10 hospitals across two 75 regions of Ethiopia as part of Safe Surgery 2020, an initiative to improve surgical care in the 76 country [19]. Since 2018, the electronic platform DHIS2 has been used to report and aggregate 77 these indicators. Informed by the evaluation of the first five-year surgical strategic plan (SaLTS) 78 in 2020, the Ethiopian Federal Ministry of Health has now initiated the second stage of this 79 strategy, SaLTS II, in 2021. The SaLTS II plan [20] outlines the approach to meet surgical 80 metric goals by the year 2025, that include increased surgical volume and providers in line with 81 international standards, POMR < 2%, and improved access to care within two-hours. To 82 evaluate the sustainability of the SaLTS data system and ensure its utility in monitoring progress 83 towards these goals, this study was created to appraise these key surgical indicators.

The aim of this study is to investigate the data management practices and assess the quality of surgical data in Ethiopia by exploring how surgical indicators are collected and reported at the hospital level since their national implementation.

5

## 87 Material and Methods

#### 88 Study design

89 The study was designed as a multi-institution, retrospective record review with hospital 90 visits as the main source of program evaluation. A total of ten hospitals, split evenly between the 91 Amhara and Sidama regions, were visited by the research team from July-August 2022. During 92 hospital visits, surgical data practices were observed to assess the flow of information between 93 hospital registries, hospital monthly key performance indicator (KPI) forms, and the District 94 Health Information Software 2 (DHIS2) reports reviewed at the regional and national level. Data 95 owners and instruments were identified at each step. The dates of record review ranged from 96 1/1/2022 through 6/31/2022. The research team undertook a complete surgical data audit at 97 each hospital visited. Registries within the OR, surgical ward, ICU, and maternity ward were 98 reviewed by each reporting period and data points were aggregated to calculate monthly 99 indicators. Researchers met with hospital quality improvement officers to audit monthly KPI 100 reporting forms and final DHIS2 electronic database reports. At the Regional Health Bureaus, 101 the final data reports from the gueried hospitals visited were reviewed. At the national level, the 102 DHIS2 conglomerate data from each Regional Health Bureau was evaluated. Data triangulation 103 compared hospital to regional to national data.

#### 104 Subjects

Primary and general public hospitals who were previously involved in Safe Surgery 2020 interventions, with approval from the Amhara and Sidama Regional Health Bureau and the Ministry of Health, were selected for this research [19][21]. Amhara hospitals were further chosen based on their participation in the 2018 surgical data intervention carried out by the

6

- 109 research team. Sidama hospitals were selected according to their involvement in Safe Surgery
- 110 2020 programming. Records of patients who underwent major surgery, defined as any
- 111 procedure conducted in an operating room under general, spinal, or regional anesthesia [22],
- during their hospital stay within the study period were reviewed in this study.

#### **113 Methods of measurements**

- 114 Surgical Key Performance Indicators (KPIs) of interest were selected based on a prior
- surgical data intervention conducted at Amhara hospitals and on feedback from the Federal
- 116 Ministry of Health (FMOH). The research team selected five indicators: Surgical Volume,
- 117 Perioperative Mortality Rate (POMR), Rate of Safe Surgery Checklist Utilization (SSC), Surgical
- 118 Site Infection Rate (SSI), and Anesthetic Adverse Outcome Rate (AAO) for data analysis.
- 119 Formal definitions for each indicator were defined by the Saving Lives Through Safe Surgery
- 120 (SALTS) program [22] and are included in Table 1. For collection of data from the registries, KPI
- 121 reporting forms, and DHIS2 data, the investigators utilized Microsoft Excel forms at each
- 122 hospital during on-site visits.

Indicator	Definition
Surgical Volume	The total number of major surgical procedures performed in an
	operating theater per 100,000 population per year.
	Note: A major surgical procedure is defined as any procedure
	conducted in an OR under general, spinal, or major regional
	anesthesia.
Perioperative	The all-cause death rate before discharge among patients who
Mortality Rate	underwent a major surgical procedure in an operating theatre during
(POMR)	the reporting period.
	Note: Stratified by emergent and elective major procedures
Rate of Safe Surgery	The proportion of surgical procedures where the safe surgery
Checklist Utilization	checklist was fully implemented.
Surgical Site	The proportion of all major surgeries with an infection occurring at the
Infection (SSI) Rate	site of the surgical wound prior to discharge. One or more of the
	following criteria should be met:
	Purulent drainage from the incision wound

#### 123 Table 1. Five surgical key performance indicators of focus and definitions [23].

7

	Positive culture from a wound swab or aseptically aspirated fluid or tissue Spontaneous wound dehiscence or deliberate wound revision/opening by the surgeon in the presence of: pyrexia > 38C or localized pain or tenderness Wound pain, tenderness, localized swelling, redness or heat AND incision opened by the surgeon or spontaneously dehisced Note: A major surgical procedure is defined as any procedure conducted in an OR under general, spinal, or major regional anesthesia.
Anesthetic Adverse Outcome Rate	The percentage of surgical patients who developed any one of the following: (1) Cardiorespiratory arrest, (2) High spinal anesthesia, or (3) Inability to secure airway. Cardiorespiratory arrest defined as: cessation of cardiac activity as evidenced by: Chest compressions being performed Loss of femoral, carotid, and apical pulse with ECG changes
	<ul> <li>High spinal defined as: within 15 minutes of administration of spinal anesthesia:</li> <li>Patient experiences loss of sensation in the shoulder AND</li> <li>Need for positive pressure ventilation after administration of spinal anesthesia</li> <li>Includes any administration of spinal anesthesia extending above T4 level.</li> <li>Inability to secure airway defined as:</li> <li>Having to awaken patient due to inability to intubate</li> <li>Cardiac-respiratory arrest due to failure to intubate</li> </ul>

#### 124 Data analysis

- 125 Enumerated data from hospital registries were compared with the data in the national
- 126 database. Analysis consisted of comparing data between sources (registry, KPI reporting forms,
- 127 and DHIS2) and assessing data quality according to dimension 1 (data completeness) and
- dimension 2 (internal consistency of reported data) of the Data Quality Review (DQR)
- 129 framework [22]. Completeness of data was evaluated by reviewing the monthly KPI reporting
- 130 forms for the study period (Jan-June 2022) and documenting the number of months KPI data
- 131 was absent for each indicator. For example, if the value for surgical volume was missing for one
- 132 month at a single hospital, this was denoted as missing 1/6 of surgical volume data for the study

8

133	period. Inconsistent data was defined as the number of months within the six-month study
134	period where the registry source data did not match the DHIS2 electronic database. Following
135	FMOH guidelines, surgical indicator data was deemed inconsistent if DHIS2 data differed by
136	more than 10% of the registry data. This established verification factor for routine data quality
137	assessment is calculated by the number of recorded events from the source document (registry)
138	divided by the number of reported events in the DHIS2 report, with verification factor greater
139	than 1.1 (under-reporting) or less than 0.9 (over-reporting) deemed inconsistent [24]. The KPI
140	Safe Surgery Checklist utilization was an exception where KPI reporting forms were used as the
141	source data and matched to DHIS2 data, given this indicator is not recorded in the registry.

#### 142 Ethical approval

Institutional review board approval was obtained from Medical College of Wisconsin and
 the Ethiopian Public Health Institute for all study activities. The study investigators also received
 a letter of support from the Federal Ministry of Health.

## 146 **Results**

#### 147 Hospital characteristics

Table 2 includes hospital specific data on facility resources and characteristics for the ten study hospitals. Median catchment population was 375,000 patients (70,000-1,800,000) whereas median total hospital beds was 45 (25-145). Integrated Emergency Surgical Officers (IESOs), Master's-level health professionals intended to provide emergency and essential surgery in Ethiopia, were the predominant surgical provider at most institutions [25].

153 **Table 2. Hospital-specific characteristics.**

<sup>a</sup>General hospitals considered secondary level health care. All other hospitals are

158 primary hospitals, part of the primary level health care.

#### 159 **Data collection processes**

160 At all ten hospitals, data flow mechanisms were observed and compiled into a

161 generalized process illustrated by Figure 1. The data collection process involved recording data

- 162 elements in registries by hospital staff, then calculation of KPIs by quality improvement (QI)
- 163 officers, completing monthly KPI reporting forms, and submitting data into the electronic national
- data system (DHIS2). For the five KPIs evaluated, healthcare providers entered surgical data
- 165 into registries specific to their department, i.e. wards, ICU, or operating room. At the end of the
- 166 reporting period, the QI officers reviewed the registries and utilized the raw data to calculate key

10

167 performance indicators. If they noted any discrepancies or missing data, they would query the 168 health provider responsible for that element. KPI data collection forms for this purpose varied 169 between hospitals. The KPI data is then entered into the electronic DHIS2 and uploaded to the 170 Regional Health Bureau (RHB) for approval. KPI data at the RHB is aggregated from multiple 171 hospitals together to describe the surgical practice in the region and submitted to the Federal 172 Ministry of Health.

Figure 1. Surgical indicator data flow. Responsible data owner and reporting instrument at
each step of the data collection and reporting process. KPI = Key Performance Indicators,
DHIS2 = District Health Information Software 2.

#### 176 Surgical key performance indicators

177 From registry data collected independently, values for the five KPIs of interest were 178 calculated for each month from January to June 2022 (Tir to Sene 2014 in the Ethiopian 179 Calendar). For all ten hospitals over six-months, average monthly surgical volume was 57 cases 180 and SSC utilization was 93% (Table 3). Over one month, the mean surgical volumes were 54 181 and 59 cases per hospital in Amhara and Sidama, respectively. In Amhara, the majority of 182 hospitals reflected the regional average. In Sidama, three primary hospitals performed less than 183 15 cases each on average per month, while the two general hospitals each performed between 184 55 and 214 operations on average per month. This extrapolates to a predicted rate of 50 to 712 185 operations per 100,000 population annually at primary hospitals in Amhara, 30 to 67 per 186 100,000 in Sidama primary hospitals, and 80 to 147 per 100,000 in Sidama general hospitals 187 according to their determined catchment populations. When calculated using a standardized 188 catchment population of 1 million for primary and general hospitals, there is a predictive rate of 189 35 to 121 operations per 100,000 population annually at primary hospitals in Amhara, 4.8 to 12 190 per 100,000 in Sidama primary hospitals, and 64 to 264 per 100,000 in Sidama general

11

- 191 hospitals. Across all ten hospitals over the 6-month period there were thirteen post-operative
- 192 mortality events, for a collective POMR of 0.38% (13/3399). For the same period, twenty-seven
- 193 surgical site infections were reported for an overall inpatient SSI rate of 0.79% (27/3399). Five
- anesthetic adverse outcomes were documented for a collective AAO rate of 0.15% (5/3399).

195 **Table 3: Comparison of registries to DHIS2 data for surgical KPIs.**

196 Surgical Volume, SSC = Surgical Safety Checklist utilization, SSI = Surgical Site Infection,

197 POMR = Perioperative Mortality Rate, AAO = Anesthesia Adverse Outcome. Median surgical

volume with range for each hospital across the 6-month study period documented within

12

199	hospital registries and DHIS2 report. Total surgery site infections, perioperative mortality events,
200	and anesthesia adverse outcomes documented monthly in hospital registry and DHIS2 during
201	the study period. * aKPIs where monthly KPI forms were used as source data due to lack of
202	registry data.
203	<sup>b</sup> Denotes that Hospital 5 SSC data was calculated from four months rather than six months as

two months of KPI data were incomplete.

#### 205 Data quality

206 Data quality was assessed based on two metrics: completeness and consistency. Our 207 study found data completeness to be an average of 72% for the 10 hospitals, and 70% of 208 hospitals had consistent data for the five surgical KPIs of interest. Verification factor calculations 209 between registry and DHIS2 data, as seen in Figure 2, revealed inconsistencies (>10% 210 difference) at nine total hospitals, commonly SSI (6/10) and surgical volume (5/10). Five 211 hospitals demonstrated incomplete registry data, with the most commonly incomplete indicator 212 data for AAO, SSC, and SSI. Across all five KPIs of interest, surgical volume was the most likely 213 to be recorded within the registry and have inconsistencies between values recorded in the OR 214 registry and DHIS2 (Table 3). Of note, Sidama hospitals frequently had more inconsistent 215 surgical volume data than Amhara hospitals.

216

Figure 2. Data quality assessment of five surgical indicators. Number of hospitals out of 10
 with inconsistent (blue) and incomplete (orange) data for each KPI of focus for the 6-month
 period. SSC = Surgical Safety Checklist utilization, SSI = Surgical Site Infection, POMR =
 Perioperative Mortality Rate, AAO = Anesthesia Adverse Outcome.

13

221 After further investigation of inconsistencies between registry data and DHIS2 data, 222 national data is revealing underreported rates (verification factor >1.1) for SSI, AAO, and POMR 223 values. For POMR, 11 of the 13 events documented for all ten hospitals across 6-months were 224 recorded at Hospital 3. However, this value does not correspond to the DHIS2 data which 225 reported zero POMR events for Hospital 3 across the 6-months (Table 3). Furthermore, 1 226 POMR event observed at Hospital 9 for the reporting period did not transfer to the DHIS2 227 database but was present in the KPI reporting form. SSI rates were similarly underreported, with 228 over half of the registry-documented surgical site infections at all ten hospitals over six months 229 missing from the overall SSIs within DHIS2 (27/3399 vs 13/3399). For AAO, only Hospital 7 230 recorded 5 AAO events within their registry for the six-month period, but zero AAO events were 231 present within DHIS2 for all ten hospitals over the study period. SSC data was mostly consistent 232 between KPI forms and DHIS2 data, with the exception of Hospital 9 where median SSC 233 differed by 12.5% and Hospital 3 where the range of SSC values differed by 36% but the 234 median remained the same.

#### 235 **Discussion**

This study evaluated the process and quality of current surgical data practices in Ethiopia through five key performance indicators (KPIs) at ten hospitals in two regions over a 6month period. The evaluation occurs five years after the creation and implementation of the surgical KPI data system in conjunction with Ethiopia's national strategic plan (SaLTS) to improve surgical and anesthesia care.

Principle findings include a largely uniform mechanism for data collection and reporting
between facilities from hospital registries, to data collection forms, to the DHIS2 electronic
database. However, the lack of standardization of data collection forms and staff practices
between each hospital may be a source of discrepancies in comparing outcomes from registries

14

to DHIS2 data. Data quality was assessed based on two metrics: completeness and
consistency which were found to be above 70% for the five KPIs at all 10 hospitals. Our study
found data completeness was 72% on average for the 10 hospitals, and 70% of hospitals had
consistent data for the five surgical KPIs of interest.

Data quality varied based on the specific indicator. Surgical volume was largely complete throughout the data process. At least 3 out of 10 hospitals had incomplete data for SSI, SSC, and AAO. This is likely due to difficulty with defining and tracking the perioperative complications of surgical site infection and anesthesia adverse outcomes, as there was observed to be variation in registries and forms for recording these two indicators, mechanisms for reporting these outcomes across the data flow, and inconsistency in which hospital provider was responsible this data collection.

256 Most inconsistencies are found for SSIs and surgical volume, with at least half of 257 hospitals having inconsistent data for these two indicators. Some hospitals were not using 258 standard registries, which could lead to missed data elements. For example, SSIs were highest 259 in hospital 6 (n=14), but only a little over half of these events made it into DHIS2 (n=8). The 260 initial data intervention included a SSI registry as part of the suite of tools for collecting and 261 recording the indicators. Some hospitals had this SSI logbook to better capture this data, but 262 there was variability in use of this system as opposed to using the hospital ward registries for 263 recording infections.

The lack of or non-standardized data collection tools to transfer indicator components from the registries to DHIS2 also created a major gap in the link between these metrics. For example, Hospital 3 had the highest POMR (11 deaths) according to the registry data, but this was not accounted for in DHIS2 (0 deaths). We observed difficulty in accounting for surgical deaths from multiple different departments (ICU, multiple wards, and OR) which could explain

15

this disparity, as deaths from the ICU were left out of the data process for POMR at this
hospital. It also demonstrates the need for specifically trained personnel for data collection and
entry, as well as routine data quality checks. Apart from the different areas of data management
shortcomings due to lack of appropriate tools, there could be a high turnover of the already
trained quality improvement officers. There should also be a uniform understanding of the
primary data owners and the QI officers.

There were overall relatively low rates of complications such as SSI (0.79%), AAO (0.15%), and POMR (0.38%). It is possible that the data does not capture the full reality as outcomes are limited to inpatient events. Additionally, many of the hospitals, especially primary hospitals in Sidama, had lower surgical volume and cases were limited to cesarean-sections, which likely contributes to the lack of significant complications in these settings.

#### 280 Surgical Site Infection

For SSI, our study estimated a value of 0.79% (27/3399) across 10 hospitals, lower than the 2% value recorded by the Network for Perioperative and Critical Care (N4PCC) 2021 registry [26] and the 10.2% described in the African Surgical Outcomes Study [11]. Specifically for SSI, patients are often discharged before they will develop signs and symptoms of infection. There is currently no uniform mechanism to enumerate outpatient SSIs.

#### 286 Anesthesia Adverse Outcome

Similarly for AAO, our dataset of 3399 surgeries yielded only 5 AAO events for a rate of 0.15%. This is considerably lower than the N4PCC 2021 registry value of 3.1% [26] and closer to the AAO reported value of 0.94% in Zimbabwe [27]. The use of a multicenter cloud-based registry, in-hospital coordinators and data trainers, and utilization of an offline mobile application

16

291	for data collection most likely improved reporting compliance and identification of adverse
292	events, leading to increased AAO capture rates in the N4PCC study [26]. Variation in AAO rates
293	reported can also be attributed to variations in KPI definitions, as in Zimbabwe where an AAO is
294	defined as a critical incident and includes nausea or post-operative pain [27]. Furthermore for
295	AAO, it may be difficult to detect and diagnose complications such as high spinal anesthesia.
296	This was also the indicator with the greatest variability in recording mechanisms and data
297	ownership, likely accounting for the very low AAO, with only one hospital reporting these events.
298	Additional training for knowledge and skills may be needed in this case.

#### **299 Peri-Operative Mortality Rate**

Our study found a lower POMR at 0.38% (13/3399) than the 0.9% (9/1000) found in the N4PCC 2021 registry surveyed at 4 Ethiopian hospitals [26]. This disparity may be due to the indicators being limited to only inpatient events, thus POMR may be lower than expected as deaths for KPIs are registered only before discharge. There were also some deaths recorded in registries, which were not reported in the national data as mentioned previously. Further external audits for these complications including chart reviews and periodical follow-up surveys are recommended to understand the true state of surgical outcomes in Ethiopian hospitals.

#### 307 Surgical Volume

Calculated annual surgical volume for Sidama general hospitals is 80 to 147 operations per 100,000, 50 to 712 operations per 100,000 population at primary hospitals in Amhara, and 30 to 67 per 100,000 in Sidama primary hospitals. In our dataset, surgical volume at all ten hospitals has not yet reached the LCoGS 2030 target of 5000 surgeries per 100,000 population annually [2]. Study findings of surgical volume for Sidama general hospitals (Jan- June 2022) are consistent with Meshesha *et al.*'s surgical volume of 289 per 100,000 over a 90-day interval

17

(Sept 2020 - May 2021) for general hospitals [28]. Our study calculates higher annual surgical
volumes for Amhara and Sidama primary hospitals than the 37 per 100,000 found for primary
health care units over a 90-day interval. The Amhara primary hospitals showed an overall
increase in their surgical volume compared to the previous study during the data intervention in
2018, [30] which may be due to both growth in surgical capacity and population needs.

#### 319 Surgical Safety Checklist

320 Estimated SSC values were 93% for 3399 surgeries, consistent with the 92.1% found in 321 the N4PCC registry for 1595 surgical cases [26] and higher than the 67.6% rate reported by 322 Sibhatu et. al. 2022 [29]. Our study determined 60% of audited hospitals had complete SSC 323 data, consistent with the 60.8% of 659 checklists the latter study found to be filled completely 324 and correctly. The barriers to data collection identified at ten hospitals within the Amhara and 325 Sidama region are consistent with the findings of previous investigations into data quality within 326 the Ethiopian healthcare system. The overreporting of certain surgical KPIs, namely SSC and 327 underreporting metrics of illness or mortality was concurrent with findings from Mekebo et. al. 328 and other studies [30-32]. Our observation of data flow processes demonstrated that SSC 329 values are calculated by QI officers by selecting a sample of ten patient charts for review. At 330 certain institutions, stop-gap mechanisms were implemented to prevent the progression of 331 patient charts to the Inpatient Admission office (IPAD) until all forms including the SSC were 332 completed. Such processes might explain the disparity Sibhatu et. al found between the DHIS2 333 SSC value of 81% and the externally audited 60.8% retrospectively calculated from patient 334 charts [28]. High rates of surgical data inconsistency were a major result of this research and 335 are likely due to lack of consistent KPI reporting forms, and the considerable burden of 336 aggregating substantive data elements into complex indicators as discussed previously by 337 Adane et al 2020 [33]. Our observations were in alignment with other challenges with data

18

collection in an Ethiopian setting previously discussed including turnover of hospital staff, poor
understanding of data processes, modification or manipulation of data to compensate for the
lack of data, and technological issues with DHIS2 [30-31].

#### 341 Limitations

342 National implications of this study are limited by the small sample size (10 hospitals) and 343 limited study period (six months). Follow-up investigation using qualitative methods will provide 344 further context around the findings. Additionally, the use of registry data as primary source data 345 generates the risk that some surgical indicators not recorded in the registry were left out of our 346 analysis. Using registry data rather than performing a retrospective review of surgical patient 347 charts could underestimate issues with data quality. Mortality audits, or complication audits, are 348 another potential mechanism to capture more complete data for these outcomes [34-35]. 349 Another source of data quality inconsistency could be attributed to reporting period variability 350 between hospitals. This study utilized DHIS2 reporting periods for data auditing. Other 351 limitations include the inability to quantitatively assess the level of data correction and 352 manipulation by hospital staff following recording in the registry and prior to DHIS2 input. 353 Concern over the consequences of reporting values too high or low for a given indicator likely 354 compound this issue. The study team noted blank entries were often used to denote "0" findings 355 within data forms, challenging the ability to assess data completeness. Finally, this study was 356 unable to include hospitals involved in previous data quality interventions in Tigray because of 357 ongoing conflict and travel restrictions.

#### 358 **Recommendations**

359 Our study recommends a regular supervision mechanism focused on identifying and 360 addressing data inconsistencies. At the national level, an emphasis on the importance of data

19

quality while simultaneously ensuring no penalty for suboptimal outcomes is imperative. The study team similarly recommends at the regional level, the implementation of permanent survey teams to decrease the risk of errors and improve data quality and utilization. This system is currently in place in some regions, and initial feedback from this study has been used for this purpose. At the hospital level, more consistent quality improvement programs to emphasize the relevance of these indicators can provide an opportunity to focus on surgical complications as areas for better teamwork, while increasing data capture as a byproduct.

#### 368 **Conclusion**

369 This study demonstrates the ongoing challenges to accurate surgical data collection in a 370 resource-limited setting. Five years after the implementation of Ethiopia's surgical indicators as 371 part of their national surgical and anesthesia strategic plan, there remains difficulty with 372 capturing the true value of surgical complications such as infections and perioperative mortality. 373 While a national system for data collection and reporting was established and is imperative to 374 ongoing progress, more unified mechanisms for data transfer, ongoing training for quality 375 officers and health professionals, as well as regular audits for data consistency are needed to 376 improve the current structure. Capturing outpatient surgical outcomes as well as the 377 development of an electronic registry, which is currently in development, will lead to 378 improvements in continuing to track surgical capacity and quality in Ethiopia [21][26].

#### 379 Acknowledgments

We thank the Ethiopian Federal Ministry of Health, Sidama Regional Health Bureau, and
 Amhara Regional Health Bureau for their support and collaboration.
